

Proposed Password Management Transition

As the organization evaluates changes to its technology environment, including the transition from BMS toward ServiceNow and potential future changes to the Kaseya relationship, there is an opportunity to establish a more sustainable approach to password and credential management.

The Service Desk currently relies on IT Glue for access to credentials required for day-to-day support. Moving to a dedicated password-management platform such as Bitwarden could reduce operational dependency on IT Glue while improving credential organization, access control, accountability, and employee onboarding/offboarding.

Bitwarden Enterprise could also integrate with existing identity-management processes through Microsoft Entra ID or Active Directory. This would allow Bitwarden access to be provisioned and revoked based on organizational identity status rather than relying solely on manually maintained access. Bitwarden supports automated provisioning and deprovisioning through SCIM and Directory Connector.

This proposal is not an adoption decision. It is intended to provide an operational case for evaluating Bitwarden as a potential replacement for IT Glue's password-management functionality.

Business Problem

IT Glue currently serves as an important repository for organizational credentials. If the organization eventually reduces its dependency on Kaseya-

based services, maintaining password management through IT Glue could become less desirable or introduce additional operational dependencies.

A transition without a replacement solution could create several problems:

- Delays accessing credentials required for support
- Inconsistent credential-management practices
- Excessive or inappropriate access to sensitive credentials
- Increased manual work during onboarding and offboarding
- Difficulty maintaining visibility into credential ownership and access
- Additional operational burden for the Service Desk and IT teams

A dedicated password-management platform could address these concerns while establishing a clearer relationship between employee identity, role, and access to organizational credentials.

Proposed Solution

Bitwarden Enterprise could be evaluated as a potential replacement for IT Glue's password-management functionality.

Credentials could be organized into appropriate collections and access groups for areas such as:

- Servers and infrastructure
- Local administrator accounts
- Service accounts
- Intune and endpoint administration
- Applications and systems
- Other credentials required for IT support

Role-based access could allow employees to receive only the credentials necessary for their responsibilities.

Onboarding and Offboarding Advantage

One of the stronger operational advantages is the potential integration between Bitwarden and the organization's existing identity-management platform.

Bitwarden can use Microsoft Entra ID through SCIM or Active Directory through Directory Connector to provision and deprovision users. When a user is disabled or deactivated in the source identity system, Bitwarden can revoke the user's organizational access.

This does not mean Bitwarden would replace Microsoft Entra ID or Active Directory for disabling accounts or changing Microsoft 365/AD passwords. Those actions would remain part of the organization's identity-management process.

Instead, the benefit is that the same employee lifecycle process could also control access to the organization's password-management environment.

This could reduce the risk of a former employee retaining access to shared credentials after their primary organizational account has been disabled and reduce manual offboarding steps for the Service Desk.

Expected Operational Benefits

Improved Access Control

Role- and group-based permissions could limit credential access according to job responsibilities.

Stronger Offboarding Controls

Integration with Entra ID or Active Directory could allow Bitwarden access to be automatically revoked when an employee is disabled or deprovisioned.

Simplified Onboarding

New employees could be provisioned into the appropriate Bitwarden groups and collections based on organizational roles.

Increased Accountability

Centralized management and administrative event logging could provide greater visibility into credential access and administrative activity.

Reduced Service Desk Friction

A centralized platform could make it easier for authorized technicians to locate credentials without relying on manually maintained password lists.

Reduced Vendor Dependency

Separating password management from IT Glue could reduce the organization's dependency on a Kaseya-based platform for a function that can be handled by a dedicated solution.

Key Risks and Migration Considerations

The primary risk is migrating a large and sensitive credential repository.

Existing IT Glue data may contain outdated, duplicate, incomplete, or incorrectly categorized credentials. Migration should therefore be treated as a controlled project rather than a simple bulk import.

Initial review of the Global Administrator-side export process indicated an apparent limit of approximately 2,500 passwords per export. If confirmed, credentials could be exported in controlled groups or by organization to make the information easier to review and clean.

Additional considerations include:

- Protecting credential exports during migration

- Securely deleting temporary migration files
- Converting exported data into the approved Bitwarden import format
- Preventing duplicate or outdated credentials from overwriting current information
- Validating credentials and permissions before retiring IT Glue
- Establishing appropriate groups, collections, and access policies

Recommended Approach

A phased evaluation would minimize operational risk:

1. Discovery

Identify current IT Glue usage, credential ownership, active credentials, dependencies, and access requirements.

2. Data Preparation

Export credentials in controlled groups, remove outdated or duplicate information, and prepare the data for the approved Bitwarden import format.

3. Pilot

Migrate a limited group of organizations or credential categories. Validate credentials, permissions, onboarding/offboarding workflows, and user experience.

4. Production Migration

Migrate remaining approved credentials in controlled batches with validation after each stage.

5. Decommissioning

After all required credentials and workflows have been validated and appropriate stakeholders approve the change, securely remove migration data and retire IT Glue password-management functionality.

Stakeholder Review

Because this change involves sensitive credentials, identity management, security controls, vendor services, and operational processes, implementation should involve:

- IT Leadership
- Information Security
- Service Desk / IT Operations
- Identity and Access Management
- Change Management / CAB
- Procurement / Vendor Management

Final decisions regarding platform selection, licensing, budget, security requirements, implementation timeline, and IT Glue retirement would remain with the appropriate organizational stakeholders.

Conclusion

Moving password management away from IT Glue could provide more than a replacement for an existing tool. It could establish a dedicated credential-management platform that is better aligned with identity-based access control and employee lifecycle management.

The strongest opportunity is to evaluate Bitwarden as part of a broader onboarding, access-management, and offboarding workflow, rather than simply replacing IT Glue with another password vault.

The recommended next step is a controlled feasibility assessment and pilot. This would allow the organization to validate security requirements, data quality, migration effort, user access, and onboarding/offboarding workflows before committing to a full migration.
